Title Explanation – Incremental Computation

Generic Incremental Computation for Regular Datatypes

=

Incremental computation is an approach to improve performance by only recomputing result for changed input

Title Explanation – Example Incremental Computation

```
fib :: Int -> Int
fib 0 = 0
fib 1 = 1
fib n = fib (n - 1) + fib (n - 2)
```

Call Hierarchy

Title Explanation – Example Incremental Computation

Memoization

stores the result of a computation and returns the cached result when the same input occurs again.

Title Explanation – Example Incremental Computation

New Call Hierarchy

Function Call	Result
fib(2)	1
fib(3)	2
fib(4)	3

Cached Results

Title Explanation – Generic

Generic Incremental Computation for Regular Datatypes

=

Generic refers to *datatype-generic programming*, which is a form of abstraction that allows defining functions that can operate on a large class of datatypes.

Title Explanation – Generic Example

```
data List a = Nil | Cons a (List a) -- Haskell Notation [] | x : []
length :: List a -> Int
length Nil = 0
length (Cons _ t) = 1 + length t
data Tree a = Leaf | Node (Tree a) a (Tree a)
length :: Tree a -> Int
length Leaf = 1
length (Node l _ r) = 1 + length l + length r
```

Title Explanation – Generic Example

```
gLength :: (Generic f) => f a -> Int
gLength = ...
```

A *single* length function can be written, that can operate on lists, trees, and many other datatypes

```
> gLength (Cons 1 (Cons 2 (Cons 3 Nil)))
    2
> gLength (Node Leaf 1 Leaf)
    3
```

Title Explanation – Regular Datatypes

Generic Incremental Computation for Regular Datatypes

=

Regular datatypes are recursive datatypes, which can only recurse into themselves, such as lists, Nodeary trees, etc.

Title Explanation – Regular Datatypes Example

Regular Datatypes

```
data List a = Nil | Cons a (List a)
data Tree a = Leaf | Node a (Tree a) (Tree a)
```

Not Regular Datatypes

```
data Tree a = Empty | Node a (Forest a)
data Forest a = Nil | Cons (Tree a) (Forest a)
```

Problem statement – What is the problem?

- Memoization is dependent on the size of the input
- Becomes a problem with large recursive data structures (e.g., a Tree)

Problem statement – Example

```
data Tree a = Leaf a | Node (Tree a) a (Tree a)
sumTree :: Tree Int -> Int
sumTree (Leaf x) = x
sumTree (Node 1 x r) = x + sumTree 1 + sumTree r
exampleTree = Node (Node (Leaf 1) 3 (Leaf 2)) 5 (Node (Leaf 1) 3 (Leaf 2))
```

Visual representation

```
5
/ \
3 3
/\ /\
1 2 1 2
```

Problem statement – Example

Example Tree

Tree	Result
5 / \ 3 3 /\ /\ 1 2 1 2	17
3 /\ 1 2	6

Cached Results

Solution – Using Hash function

A hash function is a process of transforming input into an arbitrary fixed-size value (i.e., digest), where the same input always generates the same output

Solution – Implementation Hash function

```
class Hashable a where
  hash :: a -> Digest

instance Hashable a => Hashable (Tree a) where
  hash (Leaf x) = concatDigest [hash "Leaf", hash x]
  hash (Node 1 x r) = concatDigest [hash "Node", hash 1, hash x, hash r]
```

Solution – Storing the Digests

A Merkle Tree is a data structure which integrates the digests within the data structure

```
data TreeH a = LeafH Digest a
             | NodeH Digest (TreeH a) a (TreeH a)
merkle :: Tree Int -> TreeH Int
merkle 10(\text{Leaf x}) = LeafH (hash 1) x
merkle b@(Node l x r) = NodeH (hash b) l' x r'
  where
    1' = merkle 1
    r' = merkle r
```

Solution – Using Digests

```
sumTreeInc m (LeafH d x) = case lookup d m of
  Just z -> (z, m)
  Nothing -> (x, insert d x m)
...
SumTreeInc
```

Solution – Updating the Digests

The *Zipper* is a technique for keeping track of how the data structure is being traversed through

todo

Generic Programming – Pattern Functors

Generic Programming – Merkle

```
type Merkle f = Fix (f :*: K Digest)

class Hashable f where
  hash :: f (Merkle g) -> Digest

instance ...

merkle ...
```

Experiments - Method

```
cataSum (Leaf x) = x
cataSum (Node 1 x r) = x + cataSum 1 + cataSum r
genericCataSum = cataMerkle
  (\case
    Leaf_ x -> x
    Node_1 x r \rightarrow 1 + x + r
incCataSum = cataMerkleMap
  (\case
    Leaf_ x -> x
    Node 1 \times r \rightarrow 1 + x + r
```

Experiments – Results

I am fast as f*ck boy!
